# Summary & Conclusions

- Miricorilant, as a selective glucocorticoid receptor modulator (SGRM), may offer a promising new strategy for the treatment of NASH/MASH
- Miricorilant 100 mg twice-weekly was safe, welltolerated, and resulted in reduced LFC and improved hepatic, lipid, and glycemic markers
- This dosing schedule provided a gradual reduction in liver fat of ~30% over 12 weeks without an associated rise in hepatic transaminase levels
- Daily miricorilant (50–150 mg) produced greater reductions in LFC by week 6 but was more likely to result in concurrent transaminase elevation requiring study drug interruption or discontinuation
- Additionally, miricorilant 150 mg twice-weekly is being evaluated in the phase 1b study
- Miricorilant 100 mg twice-weekly will be evaluated further in a placebo-controlled phase 2b study (MONARCH) to assess miricorilant's efficacy and safety for the treatment of biopsy-confirmed NASH

LFC, liver fat content.

The authors thank all those who are participating in this study: The study patients and their families, the investigators, and the sponsor team.

# Miricorilant (CORT118335)

## Phase 2a Study of Miricorilant in Patients with Presumed NASH (NCT03823703)

## Key eligibility criteria

- Liver fat content by
- MRI-PDFF ≥8%

# Background

### • Cortisol activity has been implicated in the development and progression of NAFLD (also known as MASLD)<sup>1,2</sup>

Cortisol is a natural steroid ligand for the glucocorticoid receptor (GR) Binding of cortisol to the GR increases availability of energy substrates, such as FFAs, for daytime activities and response to stress

• Cortisol can contribute to excess FFAs in the liver by increasing FFA uptake and de novo lipogenesis

• An oral, nonsteroidal SGRM

• Acts as a mixed agonist/antagonist of the GR and antagonist of the MR<sup>3</sup>

• May improve hepatic steatosis by selectively modulating cortisol activity in the liver

• Reversed and prevented liver steatosis by

preventing hepatic lipid accumulation, and showed reductions in inflammation and fibrosis stage and NAS in preclinical models of NAFLD/NASH (also known as MASH)<sup>4</sup>

• A double-blind, multi-center, placebo-controlled, randomized 3-arm phase 2a study to assess the safety and efficacy of miricorilant in reducing LFC in patients with presumed NASH

Adult patients (18–75 years) with presumed NASH were randomized 1:1:1 to miricorilant 600 mg daily, miricorilant 900 mg daily, or placebo for 12

Miricorilant treatment for 30–44 days resulted in large, rapid reductions in LFC in 4 patients  $(-39\% \text{ to } -74\% \text{ reduction})^5$ These 4 patients experienced concurrent elevations in serum ALT and AST levels (>5× ULN) leading to study termination by the

No significant change in ALP or bilirubin levels occurred

No patient met Hy's Law criteria

Transaminase elevations resolved rapidly in all patients upon discontinuation of miricorilant

• The phase 1b, open-label trial in adults with presumed NASH that is reported here was subsequently conducted to evaluate if significantly lower doses and intermittent dosing of miricorilant could gradually reduce LFC without a corresponding rise in liver

# b, Open-label Trial of Miricorilant in s with Presumed NASH (NCT05117489)

# Change in Liver Parameters from Baseline to Week 12

• Greatest reductions in LFC by week 6 occurred in patients receiving daily doses of miricorilant 50–150 mg (mean % change from baseline = -22.3%) However, these patients were more likely to interrupt or discontinue study drug prior to week 12 due to concurrent transaminase elevation • No significant changes in body weight were observed in any cohort, suggesting that miricorilant is a liver-targeted therapy

\*Numbers reflect patients who completed week 12; some patients discontinued prior to week 12 due to elevations in liver function tests. For cohort 1, n=7 for LFC and n=8 for ALT, AST, GGT, ALP, and bilirubin. <sup>†</sup>Responders are defined as patients who had  $\geq$ 30% reduction in LFC from baseline at any time.

## Change in LFC Among Responders With or Without ALT >3× ULN

## Safety

- Overall, miricorilant was well-tolerated
- TEAEs occurred in 82.5% (n=52) of patients, with headache being the most common • 4.8% (n=3) of patients had grade  $\ge$ 3 TEAEs
- Two serious AEs occurred (myocardial infarction; polysomy aneuploidy of chromosomes 3, 7, and 17); neither was considered related to miricorilant
- 100 mg daily) experiencing a grade 3 ALT and AST increase • These AEs were associated with rapid reduction in liver fat; ALT and AST levels returned to baseline rapidly upon discontinuation of miricorilant
- TEAEs leading to premature study drug interruption or discontinuation occurred in 22.2% of patients (n=14)
- All but one was due to rapid drop in liver fat (-16.5% to -70.2%) causing transaminase elevations Patients who restarted miricorilant did not have a secondary rise in ALT, indicating ALT increase
- was transient
- No patient met Hy's Law criteria

- Patients with a more rapid weekly rate of LFC loss by week 6 were more likely to experience a corresponding rise in ALT
- Responders with ALT >  $3 \times$  ULN had a faster decline in LFC loss (slope, -8.76) than responders without ALT >3× ULN (slope,
- Treatment with daily miricorilant was more likely to result in discontinuation of study drug prior to week 12
- Across all cohorts, responders receiving intermittent miricorilant lost LFC more gradually and were less likely to have a rise in ALT >  $3 \times$  ULN compared to daily dosing

TEAEs experienced by  $\geq 5\%$  of

# Results: Cohort 6 (100 mg Twice-Weekly) Had the Best Benefit-Risk Profile

• At week 12, mean relative reduction in LFC was -28.2% (SD, 13.5), with a corresponding decline in liver enzymes • Patients in this cohort overall had improved lipid

profiles, glycemic markers, and fibrosis biomarkers

### Reduction in LFC from Baseline to Week 12

\*Data shown for those 5 patients in cohort 6 who received  $\geq 1$  dose of study drug, remained on trial for ≥6 weeks, and had a 12 week MRI-PDFF assessment. One patient discontinued at week 6 (lost to follow-up) and is not included.

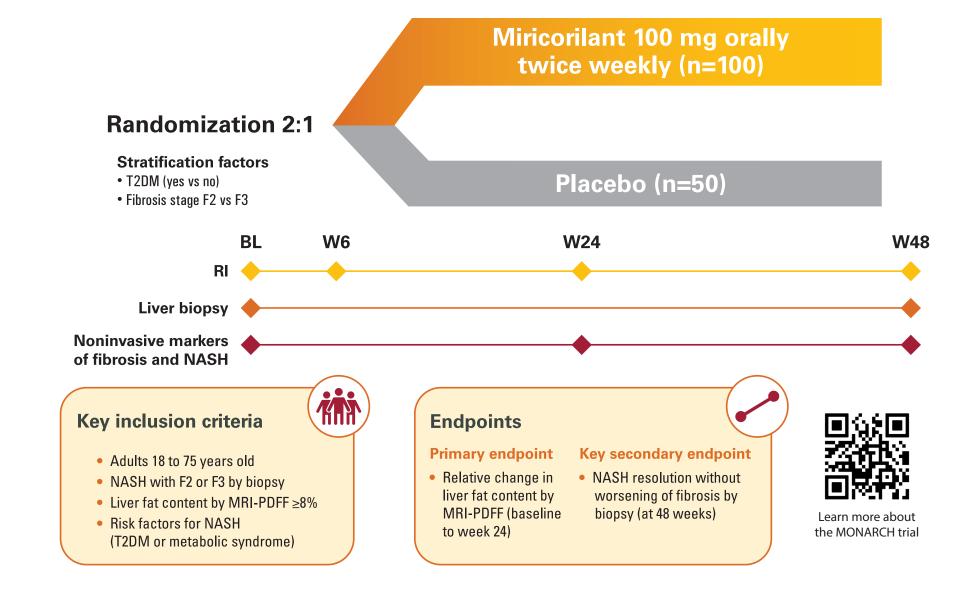

### Changes in Cardiometabolic Disease and Fibrosis Markers

| Mean change and mean %<br>change from baseline | Cohort 6      |
|--|---------------|
| Liver enzymes                                  |               |
| ALT (U/L)                                      | -4.0 (-5.7%)  |
| AST (U/L)                                      | -6.0 (-16.7%) |
| Glycemic markers                               |               |
| Fasting glucose (mg/dL)                        | -6.8 (-2.6%)  |
| Insulin (mIU/L)                                | -5.4 (-17.9%) |
| HOMA-IR  | -1.9 (-19.6%) |
| Lipid profiles                                 |               |
| LDL (mg/dL)                                    | -9.8 (-4.3%)  |
| VLDL (mg/dL)                                   | -4.0 (-5.8%)  |
| Triglycerides (mg/dL)                          | -20.8 (-6.4%) |
| Fibrosis markers                               |               |
| ELF score                                      | -0.2 (-1.8%)  |

HOMA-IR, homeostatic model assessment of insulin resistance; LDL, lowdensity lipoproteins; pt, patient; VLDL, very low-density lipoproteins.

#### 5 **MONARCH** Study Design (NCT06108219)

- A phase 2b, double-blind, placebo-controlled, randomized study evaluating miricorilant in patients with biopsy-confirmed noncirrhotic NASH
- Conducted at ~50 sites; currently enrolling
